Coding Challenge:-6

By SHREYASI REJA

Coding Challenge - Order Management System

Problem Statement:

Create SQL Schema from the product and user class, use the class attributes for table column names.

1. Create a base class called Product with the following attributes:

productId (int)

productName (String)

description (String)

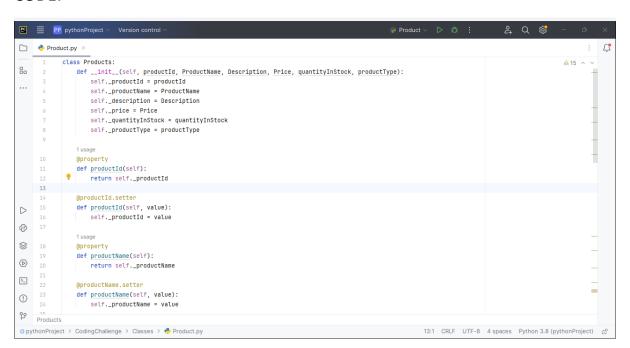

price (double)

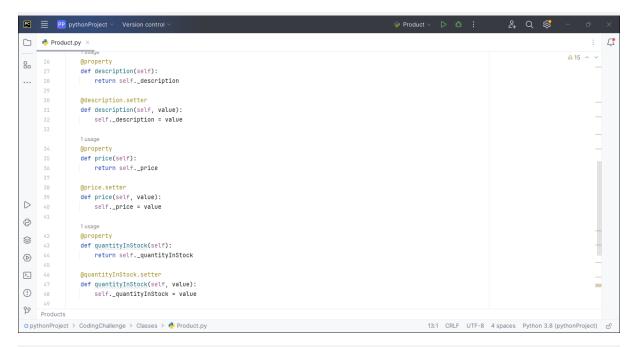

quantityInStock (int)

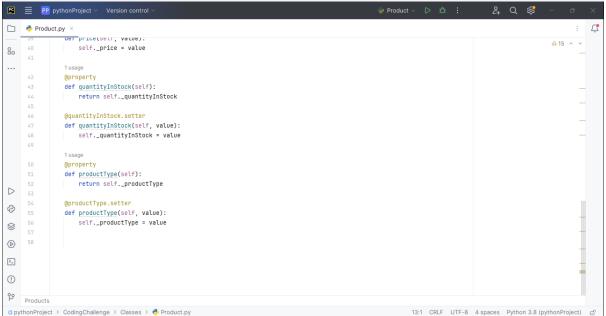

type (String) [Electronics/Clothing]

2. Implement constructors, getters, and setters for the Product class.

CODE:-

3. Create a subclass Electronics that inherits from Product. Add attributes specific to electronics products, such as:

brand (String)

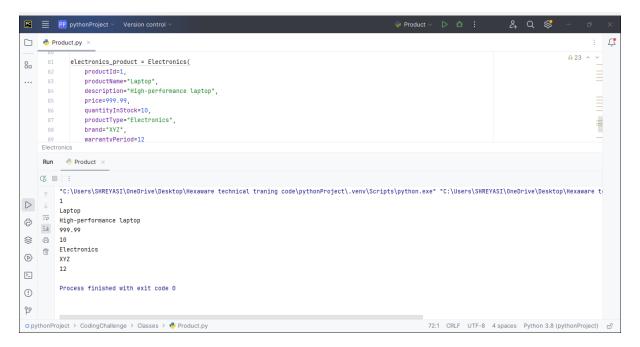

warrantyPeriod (int)

code:-

```

```

Output:-

5. Create a User class with attributes:

userId (int)
username (String)
password (String)
role (String) // "Admin" or "User"

6. Define an interface/abstract class named IOrderManagementRepository with methods for:

createOrder(User user, list of products): check the user as already present in database to create order or create user (store in database) and create order.

cancelOrder(int userId, int orderId): check the userid and orderId already present in database and cancel the order. if any userId or orderId not present in database throw exception corresponding UserNotFound or OrderNotFound exception

createProduct(User user, Product product): check the admin user as already present in database and create product and store in database.

createUser(User user): create user and store in database for further development.

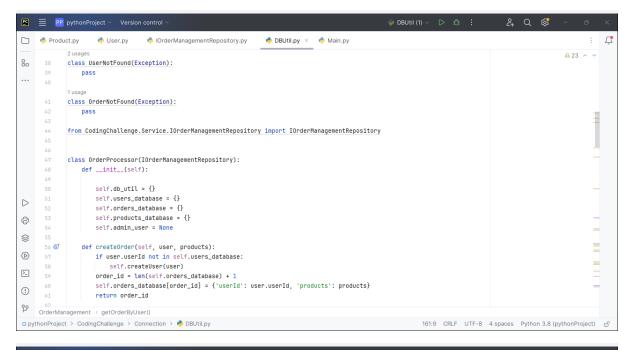

getAllProducts(): return all product list from the database.

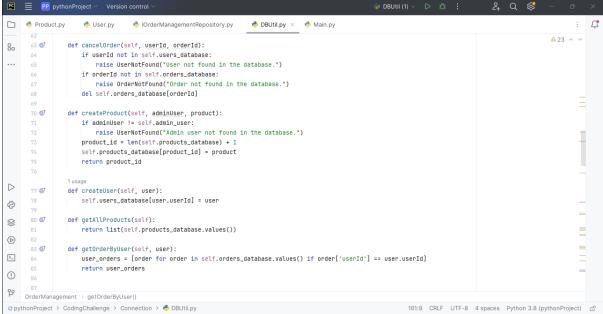

getOrderByUser(User user): return all product ordered by specific user from database.

Code:-

```
Product.py
                                 IOrderManagementRepository.py ×
        from abc import ABC, abstractmethod
      3 class IOrderManagementRepository(ABC):
             def createOrder(self, user, products):
            def cancelOrder(self, userId, orderId):
                pass
             @abstractmethod
             def createProduct(self, adminUser, product):
             def createUser(self, user):
<del>ල</del> 18
            @abstractmethod
             def getAllProducts(self):
23
24
             def getOrderByUser(self, user):
(!) <sup>25</sup>
```

7. Implement the IOrderManagementRepository interface/abstractclass in a class called OrderProcessor. This class will be responsible for managing orders.

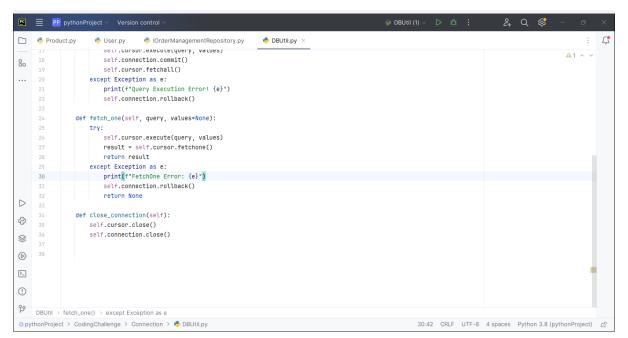

8. Create DBUtil class and add the following method.

static getDBConn():Connection Establish a connection to the database and return database Connection

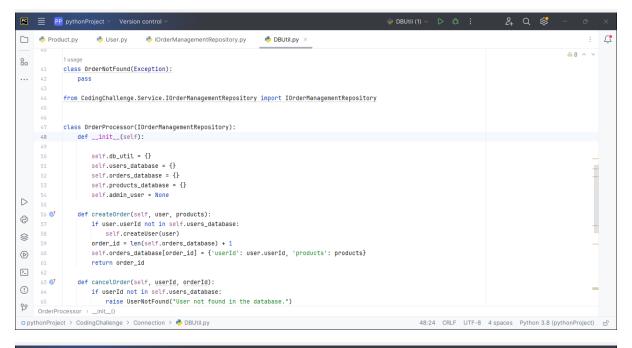

```
🤚 User.py
                                   IOrderManagementRepository.py
                                                                       DBUtil.py ×
            from mysql.connector import connect
           class DBUtil:
                def __init__(self, host, user, password, port, database):
                    self.connection = connect(
                        user=user
                        password=password,
                        port=port,
                        database=database
                    self.cursor = self.connection.cursor()
                def execute_query(self, query, values=None):
\triangleright
                    try:
                       self.cursor.execute(query, values)
8
                        self.connection.commit()
                        self.cursor.fetchall()
$
                   except Exception as e:

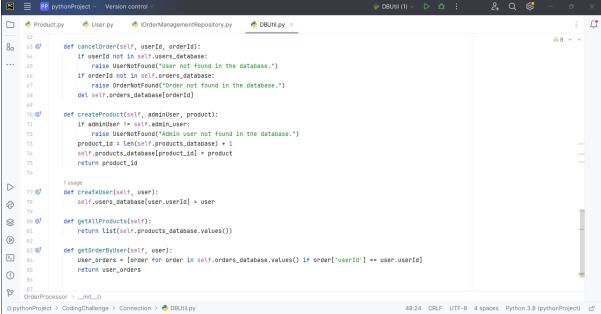

print(f"Query Execution Error! {e}")
D
                        self.connection.rollback()
                def fetch_one(self, query, values=None):
                    try:
    self.cursor.execute(query, values)
